

6. Assess the quality of the regression (visually and using numbers) in your own words.

The scatter plot shows a clear upward trend between height and weight, meaning taller people usually weigh more.

The linear regression line fits the data quite well. The R^2 value is around 0.86, which means 86% of the variation in weight can be explained by height. The RMSE is reasonable for this dataset.

Visually, the regression line lies close to most of the points, although there is some natural spread. Overall, the linear model provides a good and meaningful fit for this data.
